

Base for Fan selection
Static/ Total Pressure

Static/ Total Pressure

1. Definitions
2. Calculation of the required fan pressure
3. Use of Diffusers

Nomenclature:

Fan data sheet

- Fan total pressure
- Fan static pressure
- Fan dynamic pressure (usually not directly shown)

Ventilation System

- System static pressure rise
- System total pressure rise
- System static pressure loss
- System dynamic pressure loss

Problem:

- Values depend on the fan /system arrangement!
- “fan” and “system” values differ from each other
- e.g. Fan static pressure not similar to static pressure rise in system

Confusion, wrong selections

Fan data sheet values

Outlet ducted

⊛ A Outlet tube to balance the air flow

$$p_{\text{total}} = p_{\text{static}} + p_{\text{dynamic}} \quad \text{with } p_{\text{dynamic}} = \frac{\rho}{2} \cdot c^2$$

$$p_{\text{static}} = p_{\text{static2}} - p_{\text{static1}}$$

$$P_{\text{shaft}} = p_{\text{total}} \cdot \frac{Q}{\eta_{\text{fan}}} \quad \text{with } Q = A \cdot c$$

Free outlet

Attention:

- Total pressure for outlet ducted is different than free outlet, the outlet tube is decreasing the total pressure
- Dynamic pressure for free outlet is higher than for outlet ducted, because the cross section is reduced

Base: No pressure losses in inlet and outlet

Fan data sheet values

Outlet ducted

Free outlet

Base: No pressure losses in inlet and outlet

These are standard conditions but the real system is mostly different

Ventilation system values

Ducted in- and outlet

$$\Delta p_{\text{total system}} = \Delta p_{\text{static system}} = p_{\text{total fan}}$$

$$\Delta p_{\text{static system}} \neq p_{\text{static fan}}!!$$

The static pressure rise in a ducted in- and outlet system is given by the fan total pressure

Selection of the fan with curves for outlet ducted arrangement

Base: Same cross section at inlet and outlet

Ventilation system values

Free inlet, ducted outlet

$$\Delta p_{\text{total system}} = \Delta p_{\text{static system}} = p_{\text{total fan}}$$

$$\Delta p_{\text{static system}} \neq p_{\text{static fan}}!!$$

The static pressure rise in a free inlet and ducted outlet system is given by the fan total pressure

Selection of the fan with curves for outlet ducted arrangement

Base: Same cross section at inlet and outlet

Ventilation system values

Ducted inlet, free outlet

$$\Delta p_{\text{total system}} = \Delta p_{\text{static system}} = p_{\text{total fan}}$$

$$\Delta p_{\text{static system}} \neq p_{\text{static fan}}!!$$

The static pressure rise in a ducted inlet system is given by the fan total pressure

Selection of the fan with curves for free outlet arrangement

Base: Same cross section at inlet and outlet

Ventilation system values

Free inlet, free outlet

$$\Delta p_{\text{static system}} = p_{\text{static fan}}!!$$

This is the only case, where the static pressure rise in the system is given by the fan static pressure.

Selection of the fan with curves for free outlet arrangement

Static/ Total Pressure

1. Definitions
2. Calculation of the required fan pressure
3. Use of Diffusers

Calculation of the required fan pressure

System elements

- 1 inlet from tunnel
- 2 inlet damper
- 3 extension of cross section behind the damper
- 4 wall friction
- 5 silencers
- 6 velocity loss behind silencer
- 7 protection grill
- 8 inlet diffuser
- 9 diffuser inlet
- 10 diffuser outlet
- 11 fan isolation damper
- 12 velocity loss behind damper
- 13 silencer
- 14 velocity behind silencer
- 15 extension of cross section, velocity loss
- 16 weather protection grill
- 17 outlet to ambient

Fan has to generate enough pressure to overcome the losses of all elements. There're two types of losses:

- **Stactic pressure loss** by obstacles as grills, dampers
- **Dynamic pressure loss** by deceleration of the air flow

Calculation is done in the same manner

$$p_{i \text{ loss}} = p_{i \text{ dyn}} \times \zeta_i$$

$$p_{i \text{ dyn}} = 0,5 \times \rho \times c_i^2$$

Calculation of the required fan pressure

System elements

- 1 inlet from tunnel
- 2 inlet damper
- 3 extension of cross section behind the damper
- 4 wall friction
- 5 silencers
- 6 velocity loss behind silencer
- 7 protection grill
- 8 inlet diffuser
- 9 diffuser inlet
- 10 diffuser outlet
- 11 fan isolation damper
- 12 velocity loss behind damper
- 13 silencer
- 14 velocity behind silencer
- 15 extension of cross section, velocity loss
- 16 weather protection grill
- 17 outlet to ambient

If all the losses for all elements are calculated,
the required fan pressure will be:

$$p_{\text{fan required}} = \sum_{i=1}^{17} p_{i \text{ loss}}$$

$p_{\text{fan required}} = p_{\text{total fan}}!$

**Fan would be selected for total pressure
with curves for ducted outled arrangement**

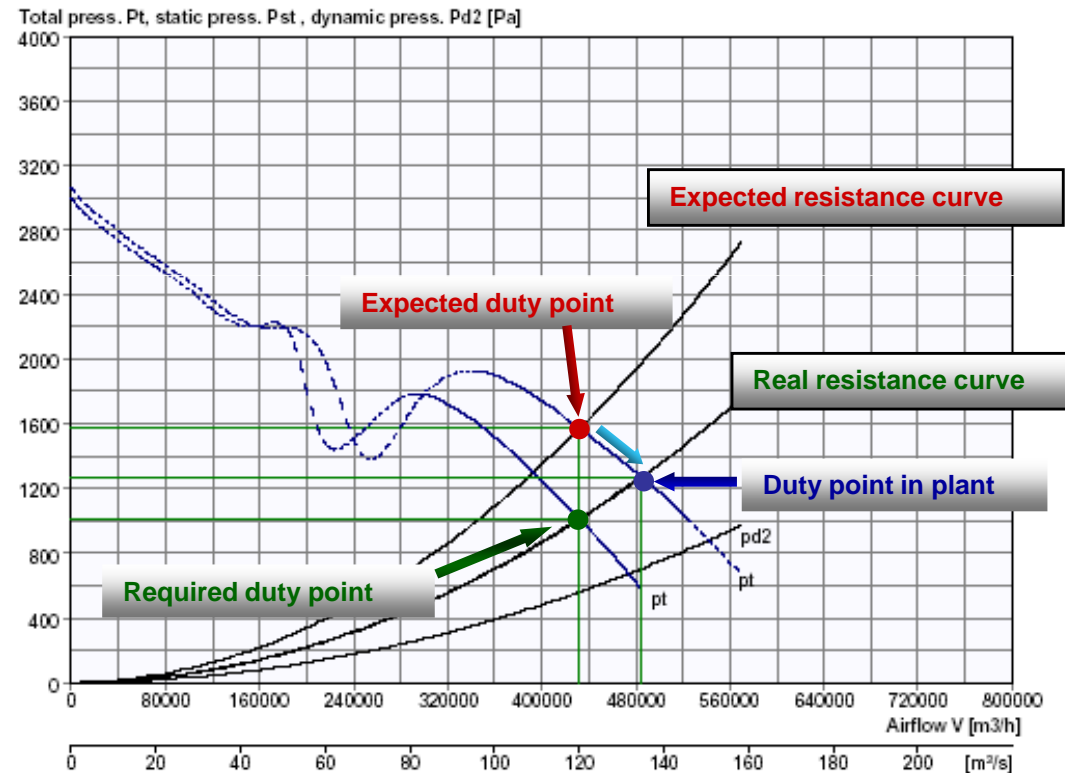

Calculation of the required fan pressure

If Selection is done for “static pressure” instead of “total pressure”

Consequences:

- Oversized fans
- Oversized electrical system
- **Waste of investment costs**

- Fans would not be designed for the correct duty point
- Optimum efficiency at real duty point not assured,
- **Waste of energy and operational costs**

Static/ Total Pressure

1. Definitions
2. Calculation of the required fan pressure
3. Use of Diffusers

Diffusers convert dynamic pressure to static pressure

Diffusers are the most efficient way to decelerate air flow, but there'll always be a pressure loss depending on the diffuser design and the inlet conditions

Consequences of the diffuser

Reduction of total pressure

Reduction of dynamic pressure

Increase of static pressure

Diffusers characteristics downstream of a fan

Downstream of a fan the velocities are not uniform. Standard literature to calculate the diffuser efficiency is not 100% accurate.

Consequences of the diffuser

Reduction of total pressure

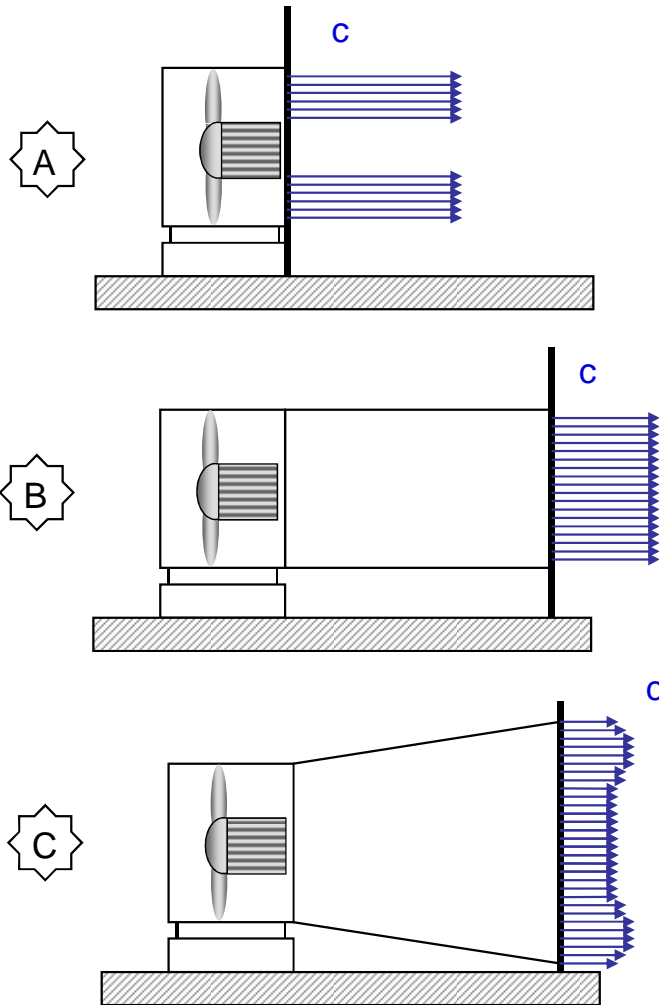

Reduction of dynamic pressure

Increase of static pressure

WITT & SOHN conducted tests to detect the performance curves of fan/diffuser units. Separate calculations of diffusers are not required!

Case study, fan selection for static pressure

- A: fan free outlet**
- B: fan outlet ducted**
- C: fan with diffuser**

- Maintain a diffuser angle of max. 7° to obtain optimum diffuser efficiency
- For reversible fans use **always** diffusers **on both sides** (otherwise stall operation in reverse!)

Case study, fan selection for static pressure

No.	Dimensions		Performance				
	Size of impeller (inlet) [mm]	Size of diffuser/duct (outlet) [mm]	Q [m ³ /s]	D _p _{tot} [Pa]	D _p _{dyn} [Pa]	D _p _{st} [Pa]	P _{shaft} [kW]
[1]							
A	2000		65	1201	401	800	118
B1	2000	2000	65	1057	257	800	97
B2	1800	1800	65	1192	392	800	108
C	1800	2000	65	1057	257	800	94

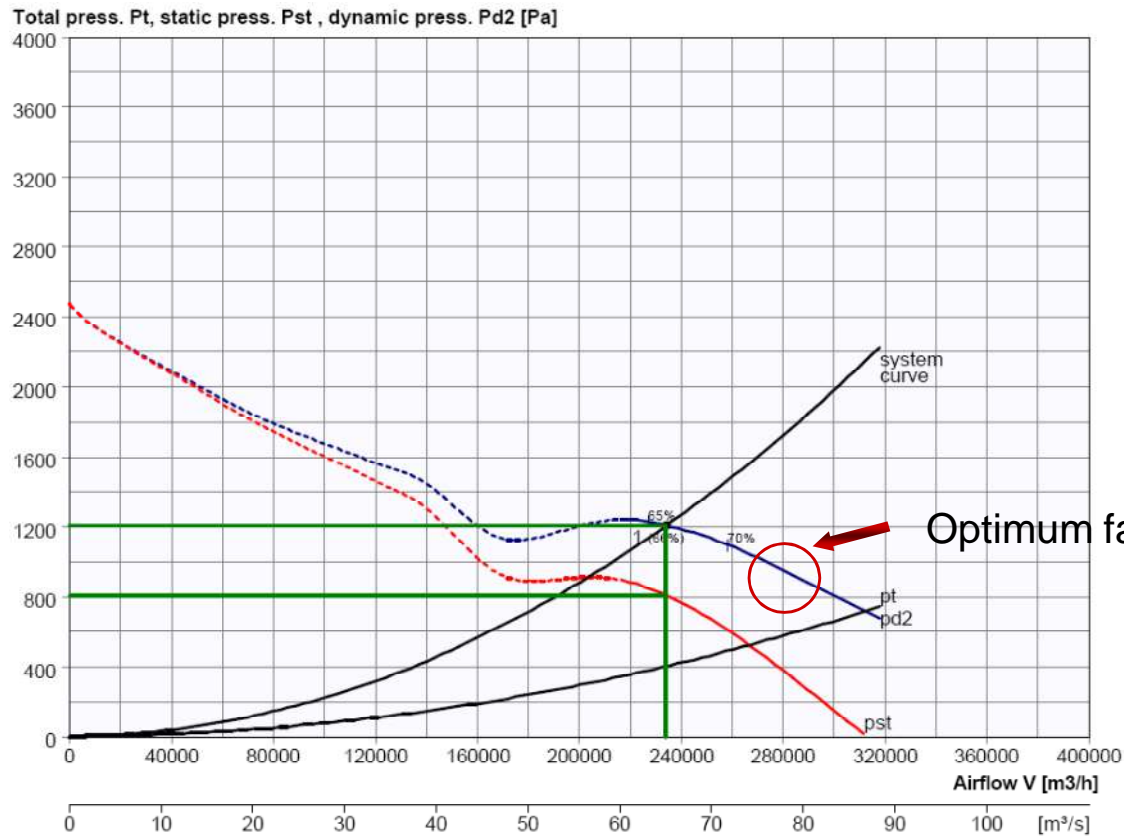

Optimum is solution C

- low dynamic pressure,
- diffuser losses compensated, since fan is operated at optimum efficiency

Use of diffusers

Case study, fan selection for static pressure

A: fan free outlet

Operation point is very close to STALL. A smaller fan may help but as a consequence the air velocity, the pressure and the power consumption will increase.

Use of diffusers

Case study, fan selection for static pressure

B: fan outlet ducted

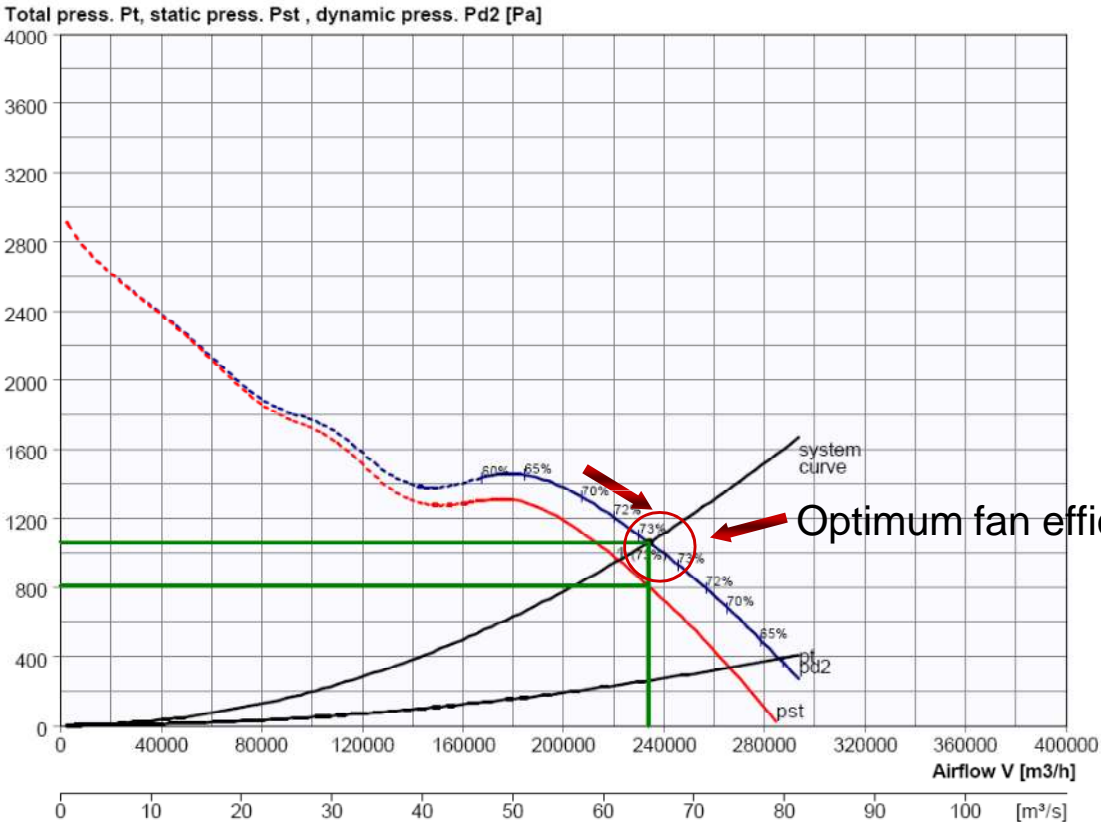

Reduced total pressure distance to STALL enlarged but still not optimal. Fan is not operated at optimum efficiency

Use of diffusers

Case study, fan selection for static pressure

C: fan with diffuser

Large distance to STALL
Fan is operated at optimum efficiency
Recommended selection

Use of diffusers

Case study, final overview with cost

No.	Dimensions		Performance			Costs	
	Size of impeller [mm]	Size of diffuser / duct [mm]	Q [m³/s]	D _{p_{st}} [Pa]	P _{shaft} [kW]	Investment	Operation
A	2000		65	800	118	100,0%	121,6%
B1	2000	2000	65	800	97	100,0%	100,0%
B2	1800	1800	65	800	108	85,0%	111,3%
C	1800	2000	65	800	94	85,0%	96,9%

Optimum is solution C

- **Lowest investment and operation costs**
- **Best aerodynamic characteristics**

Summary

- Take care of the definitions, Fan static pressure not similar to static pressure rise in system
- **If pressure losses for all elements have been calculated, the fan selection has to be for total pressure**
- **Clients are often asking for fan static pressure although they require fan total pressure, there's a large potential to reduce costs**
- If fans have to be selected for fan static pressure **(mostly not needed!)**, diffusers would reduce the fans cost (by reducing the fan size)
- The use of diffusers would reduce the risk of STALL
- Diffuser have to be designed correctly, max. angles have to be respected
